Abstract

Background: Research on social determinants of health suggests that not all people with Parkinson's Disease (PD) have been equally impacted by the COVID-19 pandemic. Therefore, this study examines the influence of individual and structural determinants on the perceived health care situation during the Covid-19 pandemic in Germany.

Methods: Analyses rely on an anonymous survey carried out as part of the abbreviation iCARE PD missing (iCARE-PD)-project. Within the scope of the project, a 49-items questionnaire was developed which aimed at characterising the access of PD-patients to healthcare services prior and during the pandemic.

Results: 551 questionnaires were filled out from all over Germany. Satisfaction for PD-related care significantly decreased during the pandemic. Educational level, perceived expertise of healthcare providers, confidence in remote care, perceived ease of obtaining healthcare prior to the pandemic, the ability to access care prior to the pandemic, density of neurologists within the area of living and the ability to overcome barriers were indicative of higher odds to perceive unmet needs during the pandemic.

Discussion: The results of this study show that not only structural conditions determine people's access to healthcare and that people with poorer Social determinants of health (SDH) experience a greater feeling of not having received needed health services during the COVID-19 pandemic.

Conclusion: In order to learn from the pandemic in the long term, difficulties in access to healthcare must be uncovered and addressed. Further investigations into the effect of individual and structural influences on measures of healthcare experiences during the COVID-19 pandemic in the German PD-population are needed.

Keywords: Parkinson's disease; COVID-19 pandemic; health care; impact; influence; Germany; iCARE-PD

Background

The COVID-19 pandemic has presented modern societies with unprecedented challenges. The uncontrolled spread of a virus that causes potentially fatal side effects despite intensive care and the resulting necessity to reduce everyday life has afflicted societies economically and culturally. However, the impact on healthcare systems has been particularly drastic. With rising incidences, public life around the world came to a standstill and access to public services, including health care, was reduced to the bare minimum. This standstill has affected individuals in societies differently

with vulnerable groups, such as people with chronic illnesses, being particularly affected by the restrictions [?, ?, ?]. This is not overly surprising in that chronic illnesses negatively affect individual psychosocial functioning [?] often leaving affected patients in need of social, financial or physical support. People with chronic diseases are primarily dependent on ongoing medical services outside of emergencies and therefore appeared to be at high risk of undersupply during the pandemic.

The group of the chronically ill also includes people with Parkinson's Disease (PD). PD-patients show a progressive condition characterized by motor but also non-motor symptoms. A plethora of different clinical signs may emerge during the disease's course, which is why continuous therapy adjustments and need assessments by healthcare professionals are required. Recent studies have unveiled the impact of the COVID-19 pandemic on people suffering from PD [?, 1, 2, 3, ?]. What remains unclear, however, is whether all patients were equally affected by the COVID-19 restrictions.

Studies from other areas of public health research indicate very individual affection for public health crisis [4, 5]. With regard to PD-patients, individual care needs may dictate the degree of affection during the pandemic [2]. More generally, so-called Social determinants of health (SDH) may also condition the individual affection [6]. SDH are non-medical factors that influence, among other things, peoples' access to healthcare and may have effects on both individual and societal levels [7]. Well investigated SDH are, for example, income, gender or coverage for health expenses [8, 9]. The association between SDH and individuals' access to health was evident not least during the COVID-19 pandemic, such that some populations experienced greater impacts than others based on their SDH [10]. People with PD in particular are at the mercy of a good social support network, which raises the question of whether patients with poorer SDH were affected more severely by the COVID-19 crisis.

What may be considered relevant SDH is by no means universal. Rather, a context-specific consideration is required [7]. For PD, Zaman *et al.* proposed a model summarising structural and individual factors potentially influencing patients' access to healthcare [11]. Structural SDH may thereby be encompassed barriers, that PD-patients meet on a system-level when accessing healthcare, such as a lack of care coordination, limited communication between healthcare providers, disparities in health services or the unavailability of specialised services [11]. Personal and therefore individual barriers, influencing PD-patients' abilities to seek help or to engage with care providers, to reach important care services or to pay for them [11] may likewise be of great importance.

To our knowledge, it has not yet been investigated how SDH may relate to the COVID-19 pandemic on PD-patients' access to healthcare. Therefore, we examined the impact of a multitude of factors on this population with special emphasis on their access to healthcare during the pandemic in Germany.

Methods

Analyses rely on an anonymous survey carried out as part of the iCARE-PD-project (<https://icare-pd.ca/>). Within the scope of this project, a 49-items questionnaire was developed which aimed at characterising the access of PD-patients to healthcare services before and during the pandemic. The initial questions in English were translated to German and were structured in four sections: A) questions describing patients' health status (in terms of PD but also of concomitant diseases), B) questions regarding experiences with healthcare services within twelve months before the pandemic, C) questions addressing experiences with healthcare services during the COVID-19 pandemic with special emphasis on telemedicine services, and, D) questions devoted to ascertaining demographic backgrounds of participants. There were single, multiple-choice questions or open-ended questions, some of which depended upon the specific answers to previous ones. A full version of the questionnaire is included in the supplementary material.

The questionnaire was distributed nationwide using the members' e-mail newsletter of the German Parkinson Association (Deutsche Parkinson Vereinigung, DPV) between November 2020 to January 2021. The e-mail included a short invitation as well as a link to an online survey, which patients could access using a personal computer, a tablet or a smartphone. In Germany, SoSci Survey [?] served as a database for hosting the survey. Throughout the data input, the database was supervised and manually checked for plausibility.

In addition to Germany, the iCARE-PD questionnaire was also shared with patient associations in Canada, Spain, Portugal and the Czech Republic with the respective translations. In this study, we limit ourselves to data collected from German patients.

Statistical analyses

All analyses were conducted in R[12]. After estimation of descriptive statistics, satisfaction with overall PD-related care was compared before and during the pandemic using a non-parametric *sign-test* (rstatix package, <https://github.com/kassambara/rstatix/>). The two questions that were used were:

- “In the 12 months prior to the COVID-19 pandemic, overall, how satisfied are you with the way healthcare services related to Parkinson's Disease were provided?” (B17) vs.
- “Since the beginning of the COVID-19 pandemic, overall, how satisfied are you with the way healthcare services related to Parkinson's Disease are provided?” (C6).

Furthermore, using a Generalised Linear Model (GLM) we estimated the odds for worse satisfaction with PD-related care. After establishing the full model with a total of 32 predictors, we conducted a stepwise logistic regression in order to reduce the complexity leaving the most meaningful predictors for the question: “Since the beginning of the COVID19 pandemic, how often did you feel you needed healthcare for Parkinson's disease but did not receive it?” (C4). For that purpose, first missing data were imputed by taking advantage of a multivariate imputation scheme using the MICE-package [13]. We thereby assumed data missing at random and used the Predictive Mean Matching Method (PMM). After missing data imputation, stepwise reduction using a GLM with Stepwise Feature Selection (*glmStepAIC*) in both

directions from the *caret*-package [14] aimed at minimising the Akaike Information Criterion (AIC). For that, we first split all data into 80% of training and 20 % of test data and performed the stepwise regression after centering and rescaling values and applying 10-fold cross-validation. The predictions of the two models were compared with the test data using Accuracy, Area Under The Curve (AUC) and LogLoss as metrics. All data for the analyses and all analyses can be followed under <https://github.com/dpedrosac/covidPD/>

Additional data

Within the last section of the survey, participants were asked to disclose the first three of five numbers of their German postal code, which allowed for regional data containment. We concatenated resulting data with publicly available population densities^[1] and those for family doctors and neurologists^[2]. Merging the available data with the maps for postal codes^[3] resulted in maps (cf. Figure 1). Densities were stratified into five equal quantiles to allow for analyses. Moreover, the provided information of concomitant diseases (besides PD) was collated to a score – the Elixhäuser Comorbidity Score with its modification introduced by van Walraven et al. [15]; here, higher values indicate more severe disease burden. Finally, all questions were assigned to barriers to accessing health services regarding PD as described by [11] (cf. Table ?? supplementary data).

^[3]<https://www.suche-postleitzahl.org/downloads>

Results

In total, 551 questionnaires were filled out with 252 different postal codes from all 16 German regions (Bundesländer, cf. Figure 1A). Of all participants, 388 (70.4%) returned a complete questionnaire (for demographics from parts A and D of the questionnaire cf. Table 1).

Satisfaction for PD-related care significantly decreased during the pandemic. Hence, the *sign-test* for the question: “Overall, how satisfied are you with the way healthcare services related to Parkinson’s Disease are provided?” indicated lower values during the pandemic (Mdn = 1) compared to before (Mdn = 3, $p = 10^{-73}$). More than 90% of all participants stating to be rather unsatisfied or very unsatisfied with their PD-related care during the pandemic (cf. Figure 2).

To ascertain underlying reasons for dramatic declines of satisfaction, logistic regressions on question C4 (‘Since the beginning of the COVID-19 pandemic, how often did you feel you needed healthcare for Parkinson’s Disease but did not receive it?’) was performed unveiling different factors which contributed to this perception of unmet needs during the pandemic (cf. Figure 3). Thus odds to affirm this question were highly significant ($p < .001$) for those patients inferring lower levels of competence for their neurologist, with a lower ability to access PD-care before the pandemic, for patients with higher degrees of stigmatisation in healthcare and for those who did not receive healthcare services before the pandemic. A significant contribution – albeit lower with significance values $p < .05$ – were encountered for PD-patients with increasing levels of comorbidity, with perceived lower expertise of the General practitioner (GP), with higher quality of life scores retrospectively, for people with higher financial burden due to PD or who rescheduled healthcare due to financial burden before the pandemic. Finally, lack of availability of remote healthcare during the pandemic and geographical or in general more numerous barriers in access to healthcare before start of the pandemic were also indicative of higher odds to perceive unmet needs. For an illustration on significant predictors cf. Figure 3 and for the entire list of results cf. Table ?? in the supplementary material.

Starting with the entirety of 32 questions that might be predictors of affirming question “C4” (see above), using a two-way stepwise regression model these could be reduced to 7 which were: educational level, perceived expertise of general practitioner, confidence in remote care, ease obtaining healthcare prior to the pandemic, ability to access care prior to the pandemic, the density of neurologists within the area of living and the ability to overcome barriers (cf. Table 2). Markers for model comparison were indicative of similar performances in the “full model” with 32 predictors compared to the reduced one (cf. Figure 4)

Discussion

In this study we sought to investigate factors contributing to insecurity and the feeling of not having received health services during the COVID-19 pandemic in Germany. To the best of our knowledge, this has been the first time that SDH have been related to the the pandemic on access to healthcare in German PD-patients. With this study, we could demonstrate that the COVID-19 pandemic did not affect all patients equally but that structural, as well as, individual determinants massively infer on people's access to healthcare. Our results may thus enable a deeper understanding of obstacles not only during the pandemic, but in general for patients suffering from PD.

It remains undisputed that the COVID-19 pandemic has been the defining event in recent years. At a relatively early stage of the pandemic, before the availability of vaccination provided some relief for people, our data reflect people's unbiased and acute concerns regarding their own healthcare. Interestingly, a good overall performance of the German healthcare system was certified during the COVID-19 pandemic, [16], which is transferable on healthcare data in person's with PD[2]. However, it would fall short to consider subjective nature of our survey results as the sole reason for the reported insecurity. In the literature, several aspects of inadequate care are reported.

For example, it has been reported that the prescription of Multimodal Complex treatments is increasing, but that this is not available in all regions of Germany and patients sometimes have to travel long distances [17]. There is also a lack of specialized staff and financing mechanisms that could take on important tasks of integrated health care [18]. Likewise, regionally networked care approaches have not yet been implemented across the country [19], so that not all patients have access to multidisciplinary care approaches, although this would be advisable [20].

The overall picture of German health care for people with PD shows that not all patients have the same chance of accessing health care. The results of this study underline that not only structural conditions determine people's access to health-care and that people with poorer SDH experienced a greater feeling of not having received needed health services during the COVID-19 pandemic.

A look at other countries confirms that not every person with PD was equally affected by the pandemic and so it seems necessary to include personal background when investigating individual satisfaction with healthcare. Survey data from 9762 participants including 5429 person's with PD in the United States demonstrated that a disruption of daily activity was more common in those who lived alone, that person's with lower income were less likely to report alternative means of exercise or social activities, and that older person's were less likely to use alternative ways to exercise [6]. So how can these people be helped?

The role of telehealth in increasing access to care for person's with PD has been recognized [?, ?]. Based on our data, the access to telehealth decreased the likelihood of experiencing unmet care needs during the pandemic. However, there is still a long way to go in Germany [?]. Further investigation on how to increase patients confidence in telemedicine and how to overcome technological limitations (ie. lack of high speed internet), is needed. An important factor to be mindful of is that the application of telemedicine may cause unintended negative effects on health

equity [?]. Poverty and barriers to digital health literacy are some factors which may contribute to discrepancies in the future, if not addressed appropriately [?].

Therefore, it seems essential for a future-oriented Parkinson's health care to look more closely at who experiences which barriers in access to health care and how these barriers can be overcome in a crisis-proof manner.

Limitations

Despite revealing problems that patients encountered during the pandemic, the interpretation of our results requires some caution. This, the survey was an anonymous online survey so that representativeness for the German PD population is not warranted. Not only is it possible that patients filling out the questionnaire are highly selected from one of the biggest support groups in Germany, the online tool also suggests that it is more likely to be tech-savvy and therefore possibly less affected patients. In this context, it was yet surprising that the mean age of participants was almost 67 years, so that young-onset PD-patients cannot be inferred from this. Finally a limitation is also the fact that there was no way to control for misdiagnosis or the correctness of data, so that these results await confirmation in observational studies with more meticulous information on demographics.

Conclusion

In order to learn from the pandemic in the long term, difficulties in access to health-care must be uncovered and addressed. The results of this analysis showed that the COVID-19 pandemic did not affect all PD-patients equally, but that people who experienced individual and structural barriers to accessing healthcare before the COVID-19 pandemic were more affected by the COVID-19 pandemic. Therefore, it is important to examine these determinants more closely and to address them in future-oriented, resilient healthcare models. Further investigations into the effect of, as Zaman *et al.* defined, individual and structural influences on measures of health-care experiences during the COVID-19 pandemic in the German PD-population are needed.

Acknowledgements

At this point we would like to thank Dr. Mehrhoff, who provided us with the resources of the Deutsche Parkinson Vereinigung (DPV) and the entire consortium of iCARE-PD.

Funding

This research was funded as part of the research project "iCARE-PD". This is an EU Joint Programme - Neurodegenerative Disease Research (JPND) project. The project is supported through the following funding organisations under the aegis of JPND - www.jpnd.eu (Canada - Canadian Institutes of Health Research; Czech Republic - Ministry of Education, Youth and Sport of the Czech Republic; France - Agence National de la Recherche; Germany - Bundesministerium für Bildung und Forschung; Spain - National Institute of Health Carlos III; United Kingdom - Medical Research Council).

M.vM. is mentioned under the aforementioned project.

D. P. received a grant from the German Research Foundation (PE 2291-1). D.P. received payments as a consultant for Boston Scientific and as a speaker at symposia sponsored by Boston Scientific and AbbVie. D.P.'s institution, not D.P. personally, received funding from the German Federal Joint Committee (G-BA), the German Federal Ministry of Education and Research, the Horizon 2020 program of the European Commission, Boston Scientific, the Parkinson's Foundation, the Dr.-Reinfried Pohl Foundation, and the German Parkinson Association (dPV).
